Predicting Molecular Geometry

1. Draw Lewis structure for molecule.
2. Count number of lone pairs on the central atom and number of atoms bonded to the central atom.
3. Use VSEPR to predict the geometry of the molecule.

Chemistry In Action: Microwave Ovens

How does Lewis theory explain the bonds in H_2 and F_2 ?

Sharing of two electrons between the two atoms.

| | <u>Bond Enthalpy</u> | <u>Bond Length</u> | <u>Overlap Of</u> |
|--------------|----------------------|--------------------|-------------------|
| H_2 | 436.4 kJ/mol | 74 pm | 2 1s |
| F_2 | 150.6 kJ/mol | 142 pm | 2 2p |

Valence bond theory – bonds are formed by sharing of e^- from overlapping **atomic** orbitals.

Change in electron density as two hydrogen atoms approach each other.

Valence Bond Theory and NH_3

If the bonds form from overlap of 3 $2p$ orbitals on nitrogen with the $1s$ orbital on each hydrogen atom, what would the molecular geometry of NH_3 be?

If use the
3 $2p$ orbitals

Actual H-N-H
bond angle is
 107.3°

Hybridization – mixing of two or more atomic orbitals to form a new set of hybrid orbitals.

1. Mix at least 2 nonequivalent atomic orbitals (e.g. s and p). Hybrid orbitals have very different shape from original atomic orbitals.
2. Number of hybrid orbitals is equal to number of pure atomic orbitals used in the hybridization process.
3. Covalent bonds are formed by:
 - a. Overlap of hybrid orbitals with atomic orbitals
 - b. Overlap of hybrid orbitals with other hybrid orbitals

Formation of sp^2 Hybrid Orbitals

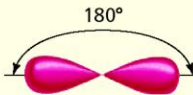

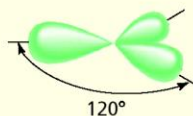

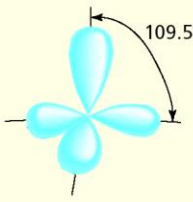

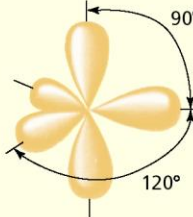

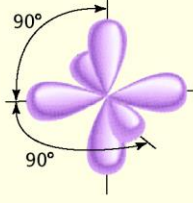

How do I predict the hybridization of the central atom?

1. Draw the Lewis structure of the molecule.
2. Count the number of lone pairs AND the number of atoms bonded to the central atom

| $\begin{array}{c} \text{\# of Lone Pairs} \\ + \\ \text{\# of Bonded Atoms} \end{array}$ | <u>Hybridization</u> | <u>Examples</u> |

$$\pi \text{ bonds} = 1$$

Experiments show O₂ is paramagnetic

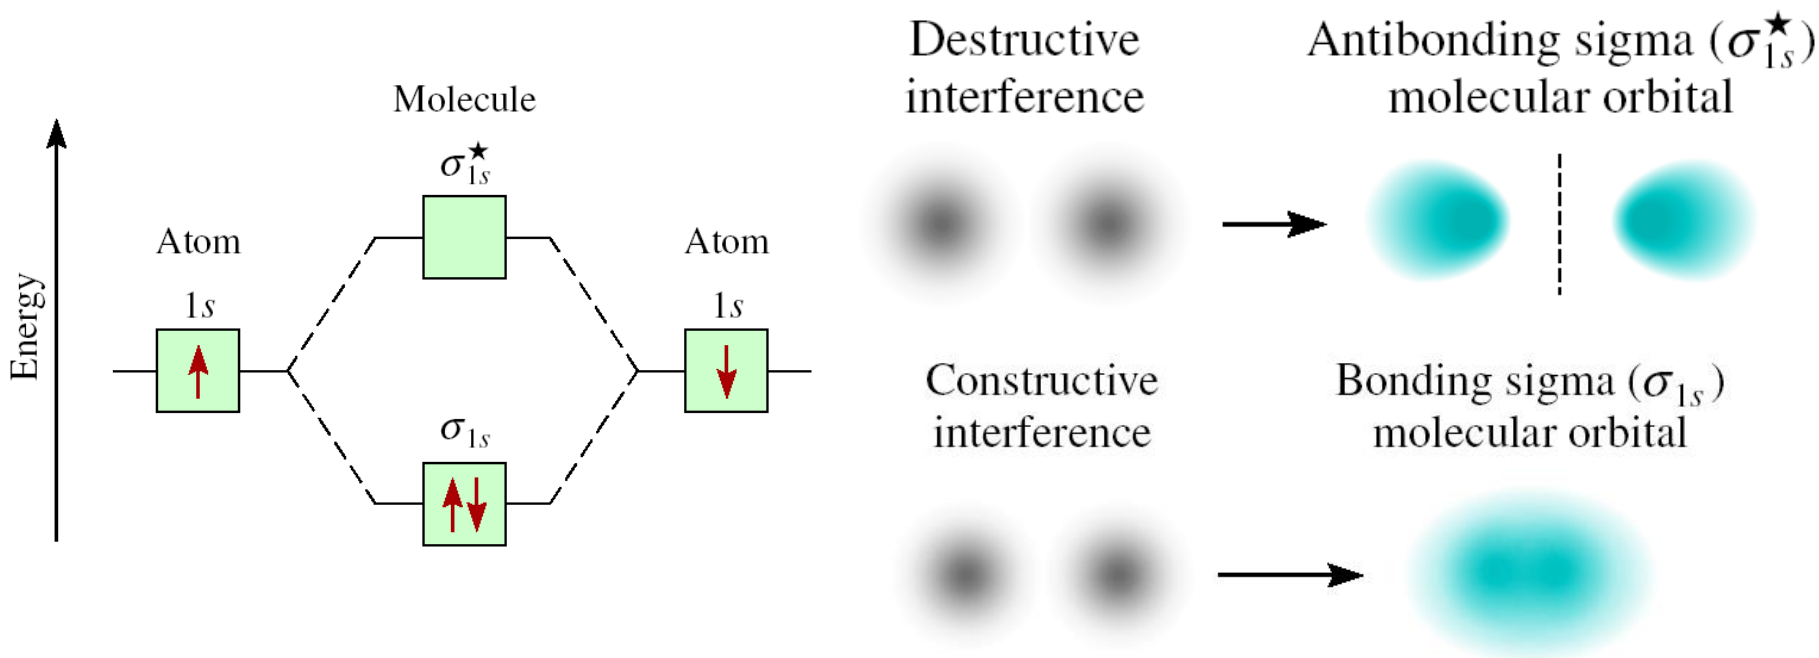

No unpaired e⁻

Should be diamagnetic

Molecular orbital theory – bonds are formed from interaction of atomic orbitals to form **molecular** orbitals.

Energy levels of bonding and antibonding **molecular** orbitals in hydrogen (H_2).

A ***bonding molecular orbital*** has lower energy and greater stability than the atomic orbitals from which it was formed.

An ***antibonding molecular orbital*** has higher energy and lower stability than the atomic orbitals from which it was formed.

Molecular Orbital (MO) Configurations

1. The number of molecular orbitals (MOs) formed is always equal to the number of atomic orbitals combined.
2. The more stable the bonding MO, the less stable the corresponding antibonding MO.
3. The filling of MOs proceeds from low to high energies.
4. Each MO can accommodate up to two electrons.
5. Use Hund's rule when adding electrons to MOs of the same energy.
6. The number of electrons in the MOs is equal to the sum of all the electrons on the bonding atoms.

$$\text{bond order} = \frac{1}{2} \left(\begin{array}{c} \text{Number of} \\ \text{electrons in} \\ \text{bonding} \\ \text{MOs} \end{array} - \begin{array}{c} \text{Number of} \\ \text{electrons in} \\ \text{antibonding} \\ \text{MOs} \end{array} \right)$$

For simplicity the σ_{1s} and σ_{1s}^ orbitals are omitted. These two orbitals hold a total of four electrons. Remember that for O₂ and F₂, σ_{2p_x} is lower in energy than π_{2p_y} and π_{2p_z} .

Delocalized molecular orbitals are not confined between two adjacent bonding atoms, but actually extend over three or more atoms.
